prelims macroeconomics

- Economic Growth in the Long-Run
- The Circular Flow of Income
- Consumption & Investment
- The National Budget Constraint
- Aggregate Demand
- The Labour Market
- Aggregate Supply
- Equilibrium of Aggregate Supply and Demand
- The Money Supply and Banking
- The Money Supply
- The Macro Model with Money: IS-LM I & II
- Inflation
- Macroeconomics in the Open Economy I, II & III

introduction

- “Is there some action a government of India could take that would lead the Indian economy to grow like Indonesia’s or Egypt’s? If so, *what*, exactly? If not, what is it about the “nature of India” that makes it so? The consequences for human welfare involved in questions like these are simply staggering: Once one starts to think about them, it is hard to think about anything else”, Robert Lucas, 1988.

important elements of long-run growth

- Technical Change (q.v. Smith's pin factory)
 - Over time, technology becomes more advanced, and hence output per worker rises;
- Increasing Quality and Variety (q.v. Schumpeter's creative destruction)
 - Over time, new products are invented which replace older qualities and varieties;
- Factor Accumulation (q.v. Ramsey on investment)
 - Over time, with sensible property rights, people accumulate capital assets (physical, human and environmental) - these factors are typically subject to diminishing returns;
- Factor Substitution (cf. Ricardo on land)
 - Over time, factors cannot earn economic rents unless their supply is restricted, even then, other factors can be used as substitutes.

Kaldor's stylised facts

- Output per worker grows over time and its growth rate does not tend to diminish; the same is true of real wages;
- Physical capital per worker grows over time;
- The rate of return to capital is nearly constant;
- The ratio of physical capital to output is nearly constant;
- The shares of labour and physical capital in national income are nearly constant;
- The growth rate of output per worker differs substantially across countries.

international labour productivity

	1820 UK=100	1870	1890	1913 USA=100	1929	1938	1950	1960	1973	1987	1998

Note: Labour Productivity is defined as GDP per man-hour

diminishing returns...

Output per worker, $y=f(k)$

...a constant saving rate...

...and a constant depreciation rate

...the Solow model

the sources of economic growth

- Consider output produced by some production function

$$Y = A \cdot F(L, K)$$

- For example, a Cobb-Douglas production function

$$Y = AK^\alpha L^{1-\alpha}$$

- If there is perfect competition, then α will be equal to the share of capital in national income, and $(1-\alpha)$ is the share of wages. We can then show that the growth of output = weighted growth of inputs + growth of total factor productivity

$$\frac{\Delta Y}{Y} = \frac{\Delta A}{A} + \alpha \frac{\Delta K}{K} + (1-\alpha) \frac{\Delta L}{L}$$

- And the growth of labour productivity = weighted growth of capital per worker + growth of total factor productivity

$$\left(\frac{\Delta(Y/L)}{Y/L} \right) = \frac{\Delta A}{A} + \alpha \left(\frac{\Delta(K/L)}{K/L} \right)$$

Solow model analysis

- The economy accumulates capital through saving, but the amount of capital per worker falls when capital depreciates physically or when the number of workers rises.
- Saving per worker (all saving is invested) is

$$S/L = sY/L = sy = sAk^\alpha$$

- Required investment per worker is a function of the existing capital stock

$$(n + d)K/L = (n + d)k$$

- In equilibrium, the capital stock will be constant when saving per worker equals required investment per worker

$$\dot{k} = sAk^\alpha - (n + d)k$$

steady-state capital and output

- When net investment is zero, we can set the previous equation to zero, which yields

$$k^* = A \left(\frac{s}{n + d} \right)^{1/(1-\alpha)}$$

- Substituting this into the production function reveals the steady-state level of output per worker

$$y^* = A \left(\frac{s}{n + d} \right)^{\alpha/(1-\alpha)}$$

- Output per worker increases with the level of technology and the saving rate and decreases with population growth and physical depreciation.

a rise in saving

slower population growth

the Golden Rule

the poverty trap

the AK model

Solow vs AK

- The Solow model has two main predictions:
 - For countries with the same steady-state, poor countries should grow faster than rich ones.
 - An increase in investment raises the growth rate temporarily as the economy moves to a new steady-state. But once the new higher steady-state level of income is reached, the growth rate returns to its previous level – there is a levels effect but not a growth effect.
- However, the AK model yields the opposite predictions – there is no convergence, and policy changes can have permanent effects.

growth accounting

productivity growth in the business sector

	TFP Growth			Labour Productivity Growth		
	1960-73	1973-79	1979-97	1960-73	1973-79	1979-97
OECD	2.9	0.6	0.9	4.6	1.7	1.7
EU	3.4	1.2	1.1	5.4	2.5	1.8
USA	1.9	0.1	0.7	2.6	0.3	2.2
Japan	4.9	0.7	0.9	8.4	2.8	2.3
Germany	2.6	1.8	1.2	4.5	3.1	2.2
France	3.7	1.6	1.3	5.3	2.9	2.2
Italy	4.4	2.0	1.1	6.4	2.8	2.0
UK	2.6	0.5	1.1	4.1	1.6	2.0

Note: Growth of total factor productivity = Growth of output minus weighted growth of inputs

total factor productivity

- A typical worker in US or Switzerland is 20 to 30 times more productive than a worker in Haiti or Nigeria.
- Between-country differences much greater than within-country differences.
- Some of this can be explained by natural resources, oil.
- Some can be explained by physical capital, but investment rates surprisingly similar across countries.
- Nor can human capital explain differences, unless investments in intangibles much bigger than we think.
- Therefore, differences in technology must matter.
- What are the barriers to efficient adoption and use of technologies across the world?

high productivity countries

- Institutions that favour production over diversion;
- Low rate of government consumption (i.e. excluding investment or transfers);
- Open to international trade;
- Well-educated workforce;
- Private ownership and good quality institutions;
- International language;
- Temperate latitude far from equator.

summary

‘Productivity Growth isn’t everything, but in the long-run, it is almost everything’, Paul Krugman, 1990.

- Unemployment and business cycles are important in explaining short and medium run growth, but play almost no rôle in the long-run: in the long-run, national output is determined by supply.
- In the long-run, the main source of rising living standards is rising output per worker.
- Rising output per worker is due to the accumulation of capital and technological progress.
